This document has been prepared in support of the Tooele Army Depot (TEAD) Site Specific Environmental Impact Statement (SSEIS) for the Chemical Stockpile Disposal Program (CSDP). This study evaluates the impact of TEAD site specific meteorological, geographical and chronological effects on the hazard distances resulting from the Credible Catastrophic Accidents (CCAs) used in the Final Programmatic Environmental Impact Statement (FPEIS). In addition, the study evaluates the impact on the total risk to the public by restricting or partially restricting disposal operations to the portion of the day when stable meteorological conditions do not exist. #### 1.0 Summary.

- a. The purpose of this study was to examine the Tooele Army Depot (TEAD) site specific meteorological, chronological and geographical effects on the hazard distances associated with the internally initiated (process dependent) disposal Credible Catastrophic Accident (CCA) scenarios used in the Chemical Stockpile Disposal Program (CSDP) Final Environmental Impact Statement (FPEIS). In addition, the study evaluated three disposal options to determine the impact on the total risk to the public by restricting or partially restricting disposal operations to the portion of the day when stable meteorological conditions do not exist.
- b. Of the 26 FPEIS internally initiated disposal CCA scenarios, only 11 continue to meet the definition of a CCA after the TEAD site specific conditions are taken into account (i.e. 10<sup>-8</sup> probability or greater of creating a downwind hazard distance which exceeded the installation boundary). The 11 CCA scenarios only exist under stable meteorological conditions therefore it is possible to eliminate the CCA scenarios by restricting disposal operations to the portions of the day when stable meteorological conditions do not exist (two hours after sunrise to on one hour before sunset). However simply restricting disposal facility operations to non-stable meteorological conditions will not prevent off-post excursions because three non-CCA scenarios create off-post excursions under neutral stability which can exist 24-hours per day. To preclude off-post excursions from these scenarios additional restrictions involving wind speed and/or solar radiation would be required.

- c. The total risk from disposal of the TEAD stockpile (including depot storage, handling and transportation as well as disposal facility operations) is very small with expected lethalities on the order of  $10^{-4}$  (0.0001). Although the total risk from unrestricted disposal operations presented the least risk to the public, the differences between the three options were within the accuracy of the calculations. The predominate risk for all the disposal options is the risk for depot storage which ranges for 65 to 76 percent of the total risk. The risk from internally initiated disposal accidents only represents a maximum of one-percent of the total risk to the public.
- CSDP disposal facility operations not be restricted on the basis of stable meteorological conditions. To help reduce the total risk to the public it is recommended that the munition disposal sequence be optimized to accelerate the disposal of the munitions which present the greatest storage risk. In addition, the feasibility of further restricting handling and transportation activities to the portions of the day when stable meteorological conditions do not exist should be evaluated. However, restricting handling and transportation activities should only be performed if the restrictions do not impede disposal operations.

#### 2.0 Introduction.

2.1 <u>Purpose</u>. To quantitatively assess and compare the risks associated with operating the proposed Tooele Army Depot (TEAD) Chemical Stockpile Disposal Program (CSDP) disposal facility on a restricted versus an unrestricted operating schedule. The study will examine the TEAD site-specific meteorological, chronological and geographical effects on the hazard distances associated with the internally initiated disposal process Credible Catastrophic Accidents used in the CSDP Final Programmatic Environmental Impact Statement (FPEIS). Different operating scenarios will then be evaluated to determine which operating scenario represents the lowest programmatic risk to the public.

#### 2.2 Background.

a. The United States has repeatedly renounced the first use of chemical weapons. However, as a deterrent to first use by other nations, the United States currently maintains a retaliatory stockpile of lethal unitary, or single component, chemical munitions. The stockpile is comprised of projectiles, cartridges, mines, rockets and bulk containers and munitions such as bombs and spray tanks, which are filled with nerve agents Sarin (GB) or VX, or blister agent Mustard (H/HD/HT). Fact sheets on the munitions and chemical agents comprising the United States stockpile of chemical munitions are contained in Appendix B. All of the chemical agents in the stockpile are at least 21 years old, with some over 40 years old. No unitary chemical agents or munitions have been manufactured since 1968.

- b. Approximately 93% of the chemical stockpile is stored at the eight locations within the United States shown in Figure 2-1, the remainder is stored on Johnston Island, which is located in the Pacific Ocean approximately 717 nautical miles southwest of Hawaii, and in the Federal Republic of Germany. The chemical stockpile at TEAD comprises approximately 42% of the United States chemical stockpile on a agent tonnage basis, making it the largest chemical stockpile in the Western Hemisphere. Although the types of agents and munitions stored at TEAD is not classified, the quantity of munitions and agents is classified for reasons of national security.
- c. Because of the increasing obsolescence of the chemical stockpile and the increasing risk which the unitary chemical agents pose to the public, the United States Congress passed Public Law 99-145, also known as the Defense Authorization Act for FY  $1986^{(1)}$ , which directed the Secretary of Defense to destroy the lethal unitary chemical stockpile by 30 September 1994 in conjunction with the acquisition of the safer binary, or two component, chemical weapons systems. In September 1988, Congress passed Public Law 100-456 $^{(2)}$ , which extended the completion deadline to 30 April 1997.
- d. The Office of the Program Manager for Chemical Demilitarization (Ofc PM Cml Demil) has been assigned the mission of disposing of the lethal unitary chemical stockpile and for ensuring that the Chemical Stockpile Disposal Program (CSDP) is conducted in such a manner as to provide maximum protection of the environment, the general public, and the personnel involved in the destruction.

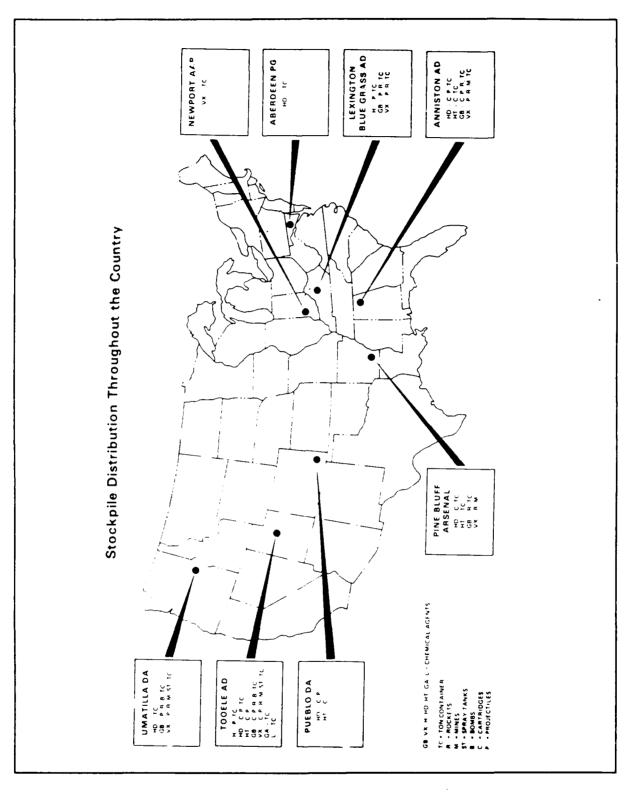

Figure 2-1: Chemical Stockpile Locations Within the United States

#### 2.3 Final Programmatic Environmental Impact Statement

- a. In accordance with the National Environmental Policy Act (NEPA), the Ofc PM Cml Demil (formally known as the Office of the Program Executive Officer-Program Manager for Chemical Demilitarization) prepared a programmatic environmental impact statement to assess the health and environmental impacts of destroying the chemical stockpile. The Final Programmatic Environmental Impact Statement was published in January 1988 with the conclusion that ensite disposal of the chemical agents and munitions was the environmentally preferred alternative (3).
- b. In Section 4 of the FPEIS, the health and environmental impacts of the disposal alternatives considered were evaluated. As the impacts of normal disposal operations for each alternative were very limited in scope and significance, the primary discriminator between the alternatives were the impacts associated with unintentional releases of chemical agent. The evaluation was based on Credible Catastrophic Accidents which were defined as accidents with a programmatic probability of  $10^{-8}$  (0.00000001) or greater. The selection of  $10^{-8}$  reflected that our society generally spends resources on mitigating accidents with a probabilities of  $10^{-5}$  to  $10^{-6}$ ; the  $10^{-8}$  reflected two orders of magnitude of uncertainty to achieve a conservative position on what accidents were of concern. Credible Catastrophic Accidents were defined by the amount of agent released under weather conditions that would result in the maximum downwind dispersion of agent. Stated another way, Credible

Catastrophic Accidents were events which had a programmatic probability of  $10^{-8}$  or greater of creating a downwind hazard distance which exceeded the installation boundary. Therefore the probability of a Credible Catastrophic Accident is a function of the probability of a accident releasing the agent and the annual frequency of the meteorological conditions dispersing the agent.

- c. In support of the FPEIS, a series of comprehensive risk assessments were performed to identify catastrophic accidents associated with each disposal alternative. The assessments were performed in two parts:
- (1) The first phase of the risk assessment was a probabilistic assessment of the frequency and magnitude of potential chemical agent releases associated with the disposal alternatives (4). After initiating events had been identified and the corresponding logic models (sequence of events) had been developed, the events were screened to ensure the median unit frequency (event per year, mile or munition/pallet depending on the accident scenario) of the each event was greater than or equal to  $10^{-10}$  and the amount of agent released created a lethal dose at a distance of 500 meters (The selection of 500 meters was based on Newport Army Ammunition Plant which has the shortest disposal facility-to-installation boundary distance of any of the chemical agent storage sites.) If the event did not meet the above criteria, it was dropped from consideration due to its low credibility or its inability to impact public safety.

- (2) The second phase of the risk assessment quantified each accident scenario in terms of programmatic accident probability, hazard distances and potential lethalities<sup>(5)</sup>.
- (a) The accident probabilities were determined by converting the median unit frequencies estimated in the first phase of the risk assessment to mean unit frequencies. The mean unit frequencies were then converted to programmatic probabilities by multiplying the unit frequencies by the appropriate number of years, miles or munitions/pallets for each installation stockpile. If the programmatic probability was less than 10<sup>-8</sup> the accident was dropped from consideration for use in the FPEIS.
- (b) Figure 2-2 is the TEAD disposal schedule which was used for the FPEIS risk assessment; the actual time required to dispose of a specific munition is classified since the munition stockpile could be determined give the published disposal rates. After the publication of the FPEIS, it was determined that it was more efficient and cost effective to increase the capacity of the TEAD CSDP disposal facility by adding a second liquid incinerator rather than constructing the Chemical Agent Munitions Disposal System (CAMDS) Bulk Facility.
- (c) The Army's D2PC atmospheric dispersion model<sup>(6)</sup> was used to estimate hazard distances resulting from each of the accident scenarios which met the criteria described in paragraph 2.3.c.(1) above. Two programmatic

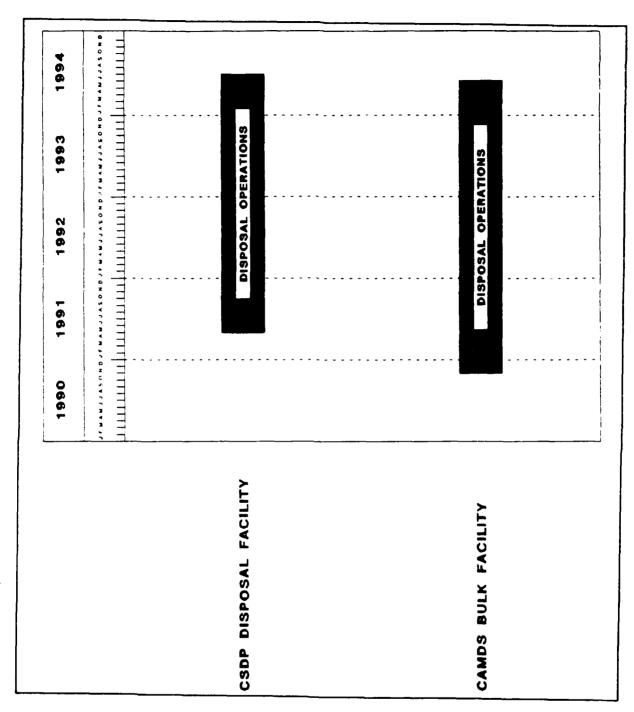

Figure 2-2: FPEIS Baseline Schedule for the TEAD Onsite Disposal Schedule

meteorological conditions were used to estimate the associated hazard distances for each of the selected accident scenarios: Conservative Most Likely (CML) and Worst Case (WC). The CML scenario represented a frequently occurring meteorological condition that resulted in relatively large hazard distances compared to other frequently occurring meteorological conditions. The WC scenario represented a credible condition that resulted in near maximum hazard distances. The meteorological conditions assigned to CML and WC are listed in Table 2-1.

Table 2-1: Meteorological Parameters Used in FPEIS Dispersion Modeling

	Meteorological	Condition
Parameter	CML	WC
Atmospheric Pressure, mm Hg	760	760
Height of Mixing Layer, meters	750	750
Wind Speed, meters/sec	3	1
Temperature, Deg Centigrade	20	30
Pasquill Stability Category	D	E
Frost Profile	0.25	0.25
Roughness Length, cm	1	1

- (d) Since frequency values could not be assigned to the programmatic meteorological conditions used in the dispersion calculations, the probabilities used to define the FPEIS Credible Catastrophic Accidents were a function only of the accident frequencies described in paragraph 2.3.b.. The result of the FPEIS risk assessment for TEAD are contained in Appendix C (Appendix II).
- 2.4. Concern with Multiple Shift Operations. A growing concern has arisen from the Department of Health and Human Services (DHHS) and the State of Utah about the advisability of operating the CSDP disposal facility on a 24-hours a day basis. This concern is based on the observation that worst-case meteorological conditions - which lead to the largest potential for human fatalities in the event an accidental chemical agent release - occur most frequently at night. The proposed solution is to limit disposal operations to meteorological conditions which will keep lethal concentrations of chemical agent resulting from a Credible Catastrophic Accident within the installation boundaries. However, the potential decrease in disposal risk may be offset by the higher risks associated with increased chemical agent and munition storage time and the potentially higher risks associated with daily start-up and shutdown of the incinerators and processes. It is this problem which this study addresses.

#### 3.0 Report Organization

This report consists of two volumes, containing the following information:

- a. Volume 1 (this document; UNCLASSIFIED) contains the description of the methodology, data and results of this study. The major sections of this volume are:
- (1) <u>Section 4</u> presents the TEAD site-specific meteorological data and actual distances from the TEAD CSDP disposal facility to the TEAD South Area installation boundary. This data is used in the dispersion and frequency calculations described in Sections Six and Seven.
- (2) <u>Section 5</u> describes the internally initiated (process dependent) FPEIS Credible Catastrophic Accidents for the TEAD CSDP disposal facility and shows their location within the disposal facility. Since the publication of the FPEIS the CAMDS bulk facility has been eliminated, therefore only the internally initiated plant operating accident scenarios for the TEAD CSDP disposal facility are used in this study.
- (3) <u>Section 6</u> describes the results of the atmospheric dispersion calculations. The Army's atmospheric dispersion model D2PC is used to determine the No Deaths (ND) hazard distances for each of the Credible Catastrophic Accidents listed in Section Five based on the meteorological data from Section Four. The results of these calculations are then compared to the

actual TEAD South Area boundary distances to determine which scenarios under which conditions result in off-post excursions.

- (4) Section 7 describes the methodology used to determine the frequency of the meteorological conditions (identified in Section Six) which permit off-post excursions, as well as the methodology used to determine the TEAD site specific Credible Catastrophic Accident probabilities. Although Section Seven lists the TEAD site specific Credible Catastrophic Accident scenarios, the scenario probabilities are classified SECRET and are therefore contained in Appendix C/Volume II.
- (5) <u>Section 8</u> describes the evaluation of three disposal scenarios, restricted disposal operations, unrestricted disposal operations, and partially restricted disposal operations, to determine which scenario presents the lowest total risk to the public. The total risk is based on the risks associated with the chemical munition storage, handling and transportation and disposal.
- (6) Section 9 contains the conclusions and recommendations of the study.
- b. Volume II (classified SECRET) consists of Appendix C and contains the classified data used or generated in this study. Specifically Volume II contains the results of the FPEIS risk analyses for TEAD, information on the TEAD stockpile, the meteorologically corrected accident probabilities, the milestone schedules and programmatic risk worksheets used in Section eight.

#### 4.0 TEAD Site Specific Data.

#### 4.1 Geography

- a. TEAD is located in north-central Utah (Figure 4-1). As shown in Figure 4-2, the depot consists of two areas approximately 15 miles apart; the chemical munitions are located in the "South Area". The "North Area" of TEAD is located in the southern part of Tooele Valley, approximately two miles from the city of Tooele and twenty-nine miles southwest of Salt Lake City. The small town of Stockton is located approximately three miles south of the North Area. The South Area occupies 19,364 acres in Rush Valley, sixteen miles south of the city of Tooele and 43 miles south-southwest of Salt Lake City. Immediately to the southwest and west of the South Area are the small farming villages of Vernon, Clover, and St John. The nearest Community of significant size, other than Tooele, is Lehi, located approximately 43 miles east of the South Area.
- b. The Tooele and Rush Valleys are bounded on the east by the Oquirrh. Mountains and on the west by the Stansbury and Onaqui Mountains. The average elevation of the Tooele and Rush valleys are 4,920 feet and 5,300 feet respectively. The two valleys are separated by a large natural dike-like formation located approximately two miles south of the North Area. The Tooele Valley is terminated approximately fifteen miles north of the Depot by the Great Salt Lake. The area surrounding the South Area is agriculture and open range land.

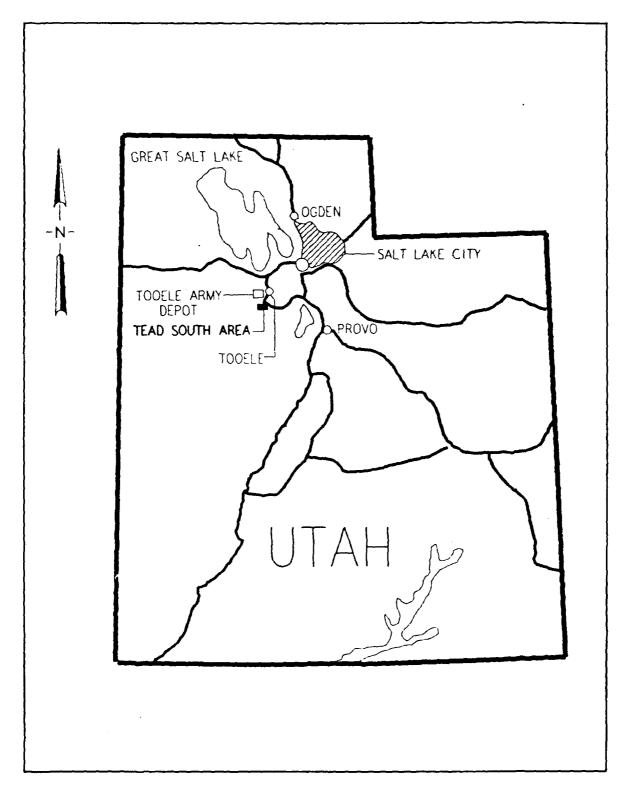

Figure 4-1: General Location of Tooele Army Depot (TEAD)

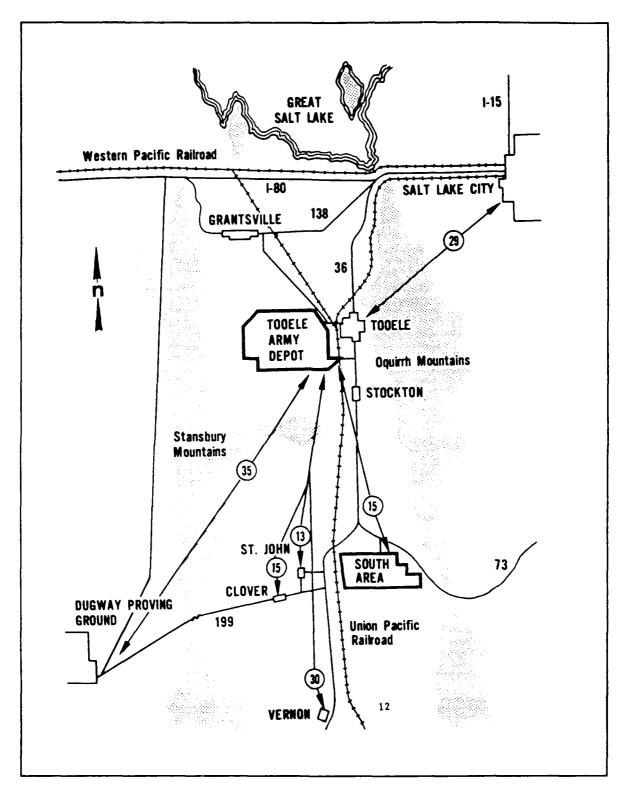

Figure 4-2: TEAD Geography

c. The chemical agents and munitions are stored in a secure compound known as "Area 10" which is located in the northwest quadrant of the South Area as shown in Figure 4-3. The CSDP disposal facility will be located adjacent to the southeast corner of Area 10, roughly in the center of the South Area. Table 4-1 lists the distances from the center of the disposal facility to the depot boundary. Figure 4-4 illustrates the facility-to-boundary distances in an array similar to a wind rose. The actual distances from the CSDP disposal facility to the TEAD South Area boundaries are 6.6 to 13 times greater than the 500 meters used in the FPEIS.

#### 4.2 Meteorology.

With the exception of the Height of Mixing Layer data, the following meteorology data was obtained from CH2M Hill, a commercial engineering consultant firm who prepared the CSDP disposal facility Resource Conservation and Recovery Act  $(RCRA)^{(1)}$  and Clean Air  $^{(2)}$  permit applications.

a. Diurnal Cycle. Diurnal cycle refers to the daily cycle of daytime and nighttime. The sunrise and sunset times were calculated using the CRSTER preprocessor based on the Julian date, longitude of the TEAD South Area and the time zone (3). The times listed in Table 4-2 are monthly averages of the daily times calculated by the CRSTER preprocessor.

#### b. Hourly Atmospheric Stability Classification.

(1) Atmospheric stability is a term which describes the amount of mixing or turbulence which occurs in the air and is divided into three broad

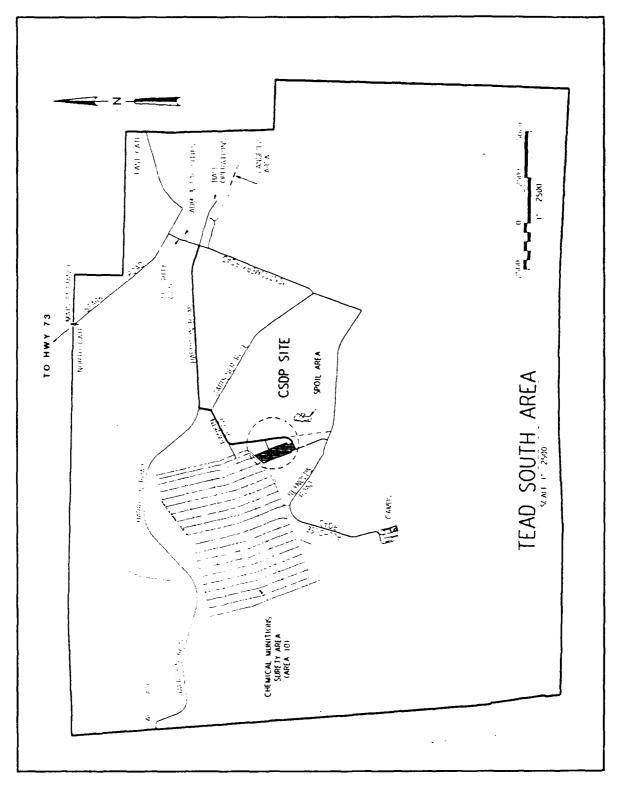

Figure 4-3: Location of CSDP Disposal Facility Within TEAD South Area

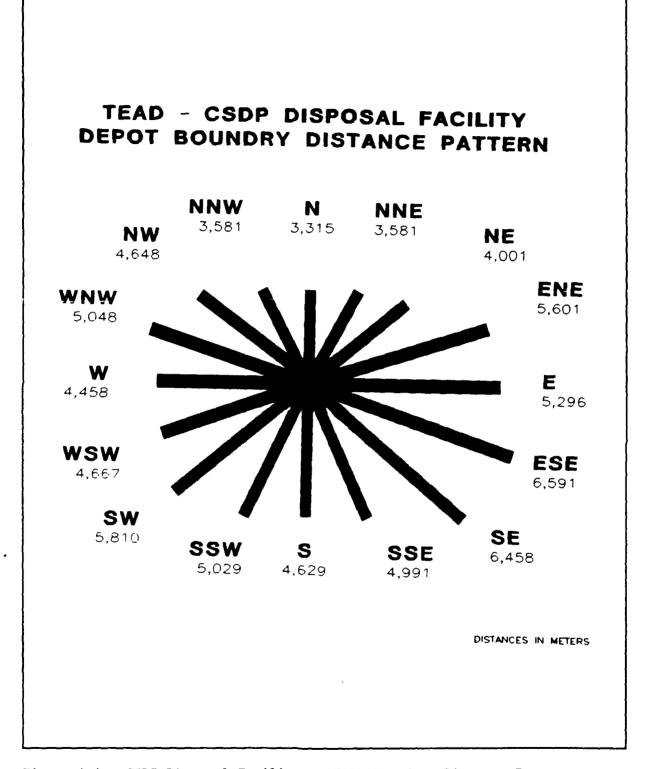

Figure 4-4: CSDP Disposal Facility to TEAD Boundary Distance Pattern

classes: unstable (lapse), neutral, and stable (inversion). The amount of turbulence in the atmosphere is dependent on two primary forces: solar radiation (thermal) and wind (mechanical). A turbulent atmosphere is said to be unstable and conversely, an atmosphere with suppressed turbulence is stable. A chemical agent cloud introduced into an unstable atmosphere will tend to dissipate quickly due to the enhanced mixing, while the suppressed turbulence in a stable atmosphere will result in larger concentrations and downwind hazard distances. An atmosphere with neutral stability will produce concentrations between that of stable and unstable.

stability is based on the research performed by Dr. F. Pasquill (4). Based on his research, Dr. Pasquill established six stability categories as follows:

(A) Extremely unstable, (B) Unstable, (C) Slightly Unstable, (D) Neutral, (E) Slightly stable, and (F) Stable. Table 4-3, gives the stability class as a function of wind speed and net radiation based on the system developed by Turner (5). The net radiation index ranges from four (4), highest positive net radiation (directed toward the ground), to minus two (-2), lowest negative radiation (directed away from the earth) and is a function of solar elevation, cloud cover and cloud height. Neutral stability occurs with overcast skies, high winds or at sunrise and sunset. The highest (F) and lowest (A) atmospheric stabilities occur during light winds with unstable conditions existing during high radiation and stable conditions existing during negative radiation. It is important to note that stable atmospheric conditions (E and F stability) only occur during nighttime which is defined as from one hour

Table 4-1: CSDP Disposal Facility to TEAD South Area Depot Boundary Distances

before sunset to one hour after sunrise; for the balance of the day, the most stable atmospheric condition which can exist is neutral or Pasquill stability category D.

(3) The hourly atmospheric stability at TEAD was calculated by CH2M Hill using the CRSTER Model based on the time of day, solar elevation,

Table 4-3: Pasquill Stability Categories as a Function of Net Radiation and Wind Speed

cloud cover and height observations and the wind speed. The first four values are used to determine the amount of solar radiation by the method developed by Turner. The amount of solar radiation is then compared to the wind speed to determine the Pasquill Stability category.

(4) Table 4-4 lists the average annual and seasonal frequencies for each Pasquill stability category based on the hourly stability calculations performed by CH2M Hill, monthly averages are contained in Table D-1. It should be noted that the CRSTER model restricts changes in stability to one class per hour, because of this conservatism, the stable atmospheric

conditions listed in Table 4-4 exist from one hour before sunset to <u>two</u> hours after sunrise. Pasquill stability category A does not occur during the fall or winter because of the low solar angle (i.e. low solar radiation). The annual 24-hour distribution of the categories is illustrated in Figures 4-5; it is important to note that Neutral or D stability occurs 24-hours a day with the highest frequencies occurring at sunrise and sunset.

### c. Wind Speed and Direction.

(1) Wind speed and direction measurements from November 1986 through October 1987 were used to generate the wind roses shown in Figures 4-6 through 4-11; the average annual frequencies are listed in Appendix D. The

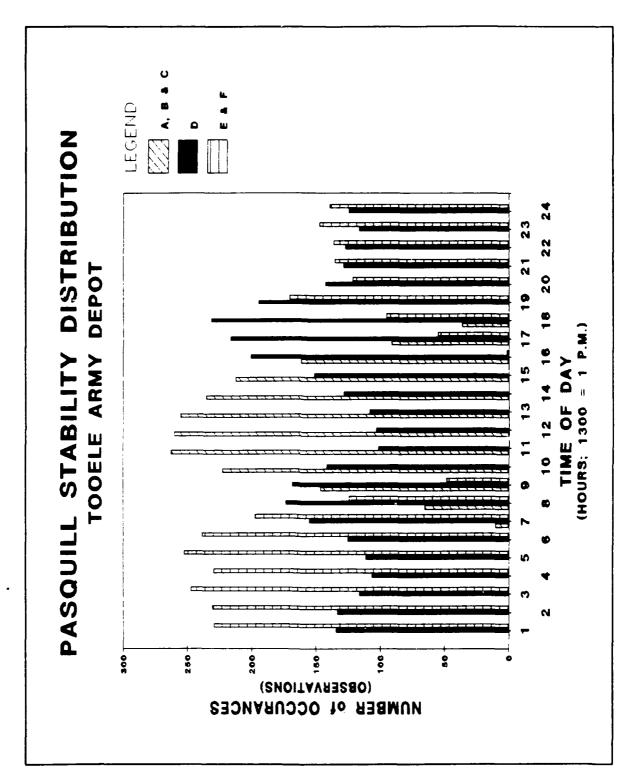

Figure 4-5: 24-Hour Pasquill Stability Distribution - Tooele Army Depot

data was collected from station number nine of the perimeter monitoring network located in the TEAD South Area in support of the Chemical Agent Munitions Disposal System (CAMDS), which is the Army's test facility for processes, procedures and equipment being considered for use in future chemical agent/munition disposal facilities. Station number nine was selected as it was the closest to the proposed location of the CSDP disposal facility.

(2) As shown in Figures 4-6 through 4-11, the prevailing winds during the day (Pasquill stability categories A - D are from the north-northwest, with a secondary peak from the south-southeast; This trend reverses itself during the night (Pasquill stability categories E and F) with the prevailing wind from the southeast and east-southeast, with a secondary peak from the north-northwest. By comparison with Figure 4-2, it is seen that the winds are aligned with Tooele and Rush valleys.

# d. Height of Mixing Layer

(1) The Mixing Layer is the portion of the atmosphere next to the surface where vigorous mixing due to thermal and mechanical turbulence occurs. Above the mixing layer an inversion, or stable air mass, exists which tends to prevent mixing with the air above. Therefore the distance from the ground to the bottom of the first inversion is called the mixing layer or depth. At distances close to the source, the mixing layer height does not affect the downwind hazard distance. However, if the agent cloud reaches the

mixing layer, the fraction of the cloud reaching the boundary is reflected back to reinforce the ground level concentration and increase the concentration within the mixing layer.

(2) Table 4-5 lists the height of the mixing layer for TEAD for each season as a function of Pasquill stability. The data was obtained from Salt Lake City airport during 1960 through 1964<sup>(6)</sup>. The height of the mixing layer depends directly upon the amount of turbulence in the lowest levels of the atmosphere - its height will increase with increased turbulence/mixing of this air, i.e. when the atmosphere becomes more unstable. In relative terms, solar radiation has more of an effect on the height of the mixing layer than wind. This explains why the mixing heights are lower in the fall and winter than in the spring and summer.

Table 4-5: Median Height of Mixing Layer for TEAD South Area

Pasquill Stability	Median Mixing Depth (meters) Season					
Category	Winter	Spring	Summer	Fall		
A	540	2310	3625	1470

#### 5.0 FPEIS Credible Catastrophic Accident Scenarios

- a. The accidents associated with disposal plant operations can be divided into two categories: internally initiated and externally initiated. Internally initiated events are dependent on the chemical munition or agent being processed in the disposal facility. Externally initiated events involve earthquakes, tornados, meteor strikes, plane crashes and other initiating events which the disposal plant operators have no control over.
- b. Except when disposal operations are stopped for an extended period of time, chemical agent/munitions will be continuously present in the disposal facility. Therefore the risks associated with externally initiated accidents will be independent of whether disposal operations are conducted on an unrestricted or meteorologically restricted basis. For this reason, only the meteorological effects on the internally initiated (process dependent) accident scenario hazard distances will be evaluated in Section Six.
- c. The descriptions of the FPEIS process dependent accident scenarios are listed in Table 5-1<sup>(1)</sup>; Figures 5-1, 5-2 and 5-3 show the location of the scenarios within the disposal facility. Table 5-2 lists the type, amount, method and duration of chemical agent release for each scenario(2); the asterisked scenarios are modeled as semi-continuous releases for two minutes (see paragraph 6.2.b(3) for further explanation). Note that not all possible chemical agents/munitions combinations are credible for each process dependent accident scenario (e.g. VX or Mustard are not listed in Table 5-2 of scenario

Table 5-1: Process Dependent Accident Scenario Descriptions

Scenario ID Number	Scenario Description
PO-abc-041	Failure to stop agent feed to Liquid Incinerator (LIC) after LIC and Pollution Abatement System, (PAS) has been shutdown. Agent vapors fill room and overload the ventilation system (carbon filters).
PO-abc-042	Metal Parts Furnace (MPF) explosion due to failure to stop fuel flow after a shutdown.
PO-abc-045	Ton container is spilled in the Explosion Containment Vestibule (ECV). Munitions Demilitarization Building (MDB) structure fails due to subsequent agent fire.
P0-abc-049	Munition detonation in Explosion Containment Room (ECR) causes structural and ventilation system failure.
PO-abc-050	Munition detonation in ECR causes structural failure, a fire, and ventilation failure.
PO-abc-051	Ton container spill in the Munitions Processing Bay (MPB). MDB structure fails due to subsequent fire.
PO-abc-052	A burstered munition is fed to the Dunnage Incinerator (DUN).

#### 6.0 Off-Post Excursion Determination.

# 6.1 <u>D2PC Atmospheric Dispersion Model</u>.

a. The Army's D2PC atmospheric dispersion model<sup>(1)</sup> was used to determine the ND downwind hazard distances resulting for each of the FPEIS Credible Catastrophic Accidents scenarios listed in Table 5-2. The ND dosages (time weighted concentrations) for chemical agents GB, VX and HD are listed in Table 6-1. The ND dosage is the largest dosage which would result in no fatalities to healthy adults breathing at a rate of 25 liters per minute which is equivalent to moderate activity.

Table 6-1: Chemical Agent No Deaths Dosage Values

Chemical Agent	No Deaths Dosage (mg-min/m <sup>3</sup> )
GB	6.0
vx	2.5
HD	100.0

b. D2PC is an air diffusion model that assumes a Gaussian plume distribution of agent in the vertical and crosswind directions as the agent disperses downwind. Extensive source term information, to include release characteristic information on the various chemical munitions in the unitary

chemical stockpile are included in D2PC. Due to the complex nature of the materials, D2PC also includes the effects on evaporation and surface type. Powerful dose conversion subroutines are included to determine both inhalation and actual exposure pathways in estimating the downwind distances and areas for selected chemical agent levels/concentrations.

c. The model assumes steady-state dispersion with straight-line cloud travel over flat open terrain; in addition, the recipient is assumed to be directly in the center of the agent cloud and is exposed to the total dosage (the entire cloud passes that point and the recipient does not move). Therefore the hazard distances estimated by D2PC are considered to be conservative (longer than would actually occur). Although this conservatism is acceptable close to the agent source, it becomes unrealistic at distances greater than 20 kilometers because of the different dispersion mechanisms involved with mesoscale meteorological circulations and diurnal variations.

#### 6.2. Hazard Distance Determination.

- a. The site specific meteorological data (wind speed and mixing layer height) from Section Four and the release parameters listed in Table 5-2 were used in the D2PC model to determine the ND hazard distances for each scenario. Except for using this data, the same modeling approach which was used by MITRE Corporation and Qak Ridge National Laboratory (ORNL) in support of the FPEIS (2) was used in this report.
  - b. Two chemical agent release modes were used to characterize the

initial dispersion of chemical agent: "instantaneous" and "semi-continuous".

- (1) Instantaneous release was used to characterize the initial dispersion of chemical agent from detonating GB filled munitions. The instantaneous D2PC source codes are based on actual open air testing conducted prior to 1969 using chemical agent filled munitions and are characterized by temperature-dependent yield factors. However, as indicated by the descriptions in Table 5-1, the actual accident scenarios are more complicated than this, involving elevated temperatures, fires, dispersion restrictions created by the demilitarization facility and processes, and other factors which invalidate the munition-based D2PC instantaneous source codes. Therefore GB detonation scenarios were modeled by specifying "non-munition" and assuming that 100% of the agent was released.
- (2) Semi-continuous release was used to characterize a chemical agent vapor release over a finite period of time. Both the quantity and duration of release are used to characterize the scenario. Typically these scenarios involved vaporization of the chemical agent by a fire. All releases were assumed to occur at ground level at ambient conditions; no credit was taken for the reduction in ground-level concentrations resulting from an elevated release (e.g. from the filter stack or for thermal plume rise) as compared to a ground level release of the same magnitude.
- (3) The D2PC instantaneous source codes for detonating HD and VX filled munitions are based primarily on aerosol or droplet dispersion.

  Although D2PC accounts for the vapor hazards from the evaporating droplets,

MITRE and ORNL felt the algorithm under estimated this agent source and elected to model HD and VX instantaneous releases as semi-continuous releases lasting two minutes<sup>(2)</sup>.

- c. An initial screening of the scenarios listed in Table 5-2 showed that no off-post excursions occurred under Pasquill stability categories A. B or C, therefore hazard distances were determined only for Pasquill stability categories D, E and F. The worksheet illustrated in Figure 6-1 was completed for each scenario. Temperature values were not required since the D2PC source codes for detonating chemical munitions were not used (see paragraph 6.2.b(1)) and none of the scenarios involved chemical agent evaporation from a spill or puddle. The wind speed values are the average speeds for each of the corresponding ranges shown in Figures 4-9, 4-10 and 4-11. The mixing layer height values are the lowest seasonal height for each Pasquill stability category; as shown in Table 4-5, the seasonal variations for Pasquill categories D through F are small, therefore the minor conservative error induced by using the lowest seasonal mixing layer height on an annual basis was determined to be acceptable given the uncertainty inherent with atmospheric dispersion modeling (+ 50%).
- d. Section One of Appendix E contains the completed worksheet for each of the FFEIS Credible Catastrophic Accident scenarios listed in Table 5-2. The maximum ND hazard distances created by each scenario under each Pasquill stability category are listed in Table 6-2; because of the reasons described in paragraph 6.1.c, computed hazard distances greater than 20 kilometers are

shown as "> 20,000 km". In all cases, the maximum distance occurs during the lowest wind speed. With each increase in wind speed, as listed in Figure 6-1, the hazard distance decreased by approximately 28 to 64 percent depending on the Pasquill stability category.

#### 6.3 Boundary Excursion.

- a. To determine the probability of off-post excursions (Section 7.0), it is necessary to determine in what direction(s) the hazard distances exceed the TEAD South Area installation boundaries. The worksheet shown in Figure 6-2 was used to facilitate the comparison of hazard distances resulting from each scenario to the South Area boundary distances shown in Table 4-1/Figure 4-4.
- b. Of the 26 FPEIS Credible Catastrophic Accident scenarios listed in Table 5-2, only 21 have the potential to create hazard distances which exceed the TEAD South Area installation boundary. The completed worksheets (Figure 6-2) for each scenario, showing under what conditions (wind direction, Pasquill stability and wind speed) each hazard distance exceeds the depot boundary, are included in Section Two of Appendix E.
- (1) No off-post hazard distances were created by Mustard filled munitions or ton containers, and except for scenario PO-CGC-042, no off-post hazard distances were created by GB filled cartridges. The specific FPEIS Credible Catastrophic Accident scenarios which did not result in off-post hazard distances were PO-KHC-042, PO-CGC-049, PO-CGC-050, PO-KHF-051 and PO-

Figure 6-2: TEAD South Area Boundary Distance Worksheet

- under Pasquill stability category F for each of the 21 scenarios, however only 15 of the 21 scenarios resulted in off-post excursions under Pasquill stability category E. GB and VX filled M55 rockets and bulk items dominated the 15 scenarios. The six scenarios which did not create off-post ND hazard distances under Pasquill stability category E were PO-CGC-042, PO-PGC-042, PO-PGC-049, PO-PCC-049, PO-PGC-050 and PO-PVC-050 which involve GB-filled cartridges, GB-filled projectiles and VX-filled projectiles.
- (3) Only three scenarios, PO-AGC-041, PO-KVC-042 and PO-SVC-042, result in off-post excursions during Pasquill stability category D. However, off-post excursions resulting from these scenarios can not be prevented by simply limiting disposal plant operations to daylight hours since Pasquill stability category D occurs 24-hours per day (Figure 4-6). To ensure these scenarios do not create off-post hazards, operations would have to be further limited to when the wind was equal to or greater than 3.1 knots (1.6 meters per second) or to when the net radiation index is equal to or greater than 2 (see Table 4-3). The later condition occurs when the solar altitude is at least 15° and the cloud cover is less than or equal to 50%.

#### 7.0 Off-Post Excursion Probability Determination.

The probability of an off-post excursion is a function of the probability of the event occurring and the total of the frequency of the meteorological conditions which cause/permit the resulting chemical agent cloud to travel beyond the installation boundary. The probabilities of the non-M55 rocket FPEIS Credible Catastrophic Accident scenarios are classified SECRET because an individual could calculate the amount of chemical agent/munitions in the U.S. stockpile given the accident frequencies contained in previously published reports. Therefore the probability of the off-post excursions based on the non-M55 rocket FPEIS Credible Catastrophic Accident scenarios are also classified. As a result, the majority of the numerical data and results for this section are presented only in Appendix C/Volume II.

# 7.1 Frequency of Meteorological Conditions.

a. The annual frequency of each meteorological condition which would permit an off-post excursion is the product of the annual frequencies of the corresponding Pasquill stability category, wind speed and direction, season, and mixing layer height. In addition, because this study is evaluating the advisability of operating the TEAD CSDP disposal facility on a 24-hour basis, the frequency of the meteorological condition is also dependent on the frequency of daytime and nighttime conditions. Equation (1) illustrates this relationship.

$$F_{\text{wind}} \times F_{\text{stability}} \times F_{\text{season}} \times (\text{Day/Night}) = F_{\text{met}}$$
 (1)

where:  $F_{wind}$  - is the annual average frequency of the wind for the selected direction, speed and Pasquill stability category. The values are listed in Tables D-5, D-6 and D-7.

- F<sub>stability</sub> is the annual average frequency for the selected

  Pasquill stability category (D, E or F). The values are

  listed in Table 4-3 as well as Tables D-5, D-6 and D-7.
- ${f F}_{f season}$  is the annual season frequency. In D2PC, the mixing layer height is determined by the season. Because the lowest seasonal mixing layer height from Table 4-5 was used on an annual basis,  ${f F}_{f season}$  equals one.
- Day/Night is the percent occurrence of the selected Pasquill

  Stability Category during daytime or nighttime. The

  diurnal distribution of Pasquill stability categories D, E,

  and F are listed in Table 7-1. The mean values from Table

  7-1 were used in frequency calculations.
- F<sub>met;</sub> is the daytime or nighttime frequency for the <u>individual</u> meteorological condition which would permit an off-post excursion.
- b. For each Pasquill stability category, there are a minimum of 32 values for  $F_{\rm wind}$ , based on wind speed and direction (see Tables D-5 through D-7). In addition, meteorological conditions which permit off post excursions exist under two (E and F) and sometimes three (D, E and F) Pasquill stability categories. Therefore the <u>total frequency</u> of meteorological conditions which

would permit off post excursions is defined by the following equation:

$$\Sigma(\Sigma(F_{wind}) \times F_{stability} \times F_{season} \times (Day/Night)) = F_{met_{total}}$$
 (2)

where  $\Sigma(F_{wind})$  - is the sum of the wind frequencies for each

Pasquill stability category.

 $\Sigma(...)$  - is the sum of the total frequencies of each Pasquill stability category.

and  $F_{met_{total}}$  - is the <u>total</u> frequency of all meteorological conditions which would permit an off-post excursion.

- c. Table 7-2 lists the total frequencies for the meteorological conditions which would result in ND hazard distance off-post excursions. The detailed spreadsheet showing the individual frequencies for each Pasquill stability category is at Section 3 of Appendix E. A third category, "Limited Daytime", is listed in Table 7-2 which represents the minimum off-post excursion frequency which can be achieved for a given scenario; under "Limited Daytime", only the frequency of off-post excursion(s) occurring under Pasquill stability category "D" are listed. The concept of "Limited Daytime" will be discussed in more detail in Section Eight.
- d. As expected, the frequency of meteorological conditions which permit off-post excursions is significantly greater at nighttime than during daytime. The ten-fold increase in off-post excursions reflects that only a small percentage of daytime hours (two hours after sunrise<sup>1</sup> and an hour before sunset) can exist under Pasquill stability categories "E" or "F".

As described in paragraph 4.2.c(4), the conservatism of the CRSTER model causes stable atmospheric conditions to exist two hours after sunrise instead of one hour as established by Dr. Pasquill.

# 7.2 Off-Post Excursion Probability

a. The probability of an off-post excursion is the product of the total frequency of the meteorological conditions which permit the hazard distance to

exceed the installation boundary (Table 7-2) multiplied by the probability of the accident scenario occurring. Table 7-3 shows the 11 FPEIS Credible Catastrophic Accident scenarios which still meet the criteria of a Credible Catastrophic Accident after the accident probability has been multiplied by the total frequency of the meteorological conditions which permit off-post excursions. The probabilities for the scenarios are listed in Table C-3 (Volume II). Fifty-five percent of these scenarios involve GB and VX filled M55 rockets with the balance being divided between GB filled ton containers (9%), GB and VX filled 155nm projectiles (18%), land mines (9%) and spray tanks (9%).

- b. Although the distribution of Credible Catastrophic Accidents in Table 7-3 occurs fairly equally between daytime and nighttime, the distribution is dependent on the agent/munition and scenario involved. The four scenarios which do not result in daytime Credible Catastrophic Accidents involve bulk items (semi-continuous release from GB filled ton containers and VX filled spray tanks) and two out-of-the three scenarios involving a detonating VX filled M55 rocket. All seven scenarios which can cause daytime Credible Catastrophic Accidents involve a detonation of a munition (scenarios 49, 50 and 52) and predominately involve GB filled M55 rockets (43%) and GB and VX filled 155mm projectiles (29%).
- c. Although seven of the 11 scenarios can result in daytime Credible Catastrophic Accidents, no Credible Catastrophic Accidents occur during

  "Limited Daytime" (daytime hours excluding stable atmospheric conditions).

  Therefore it is technically feasible to eliminate internally initiated

Table 7-3: TEAD Site Specific Credible Catastrophic Accidents

credible catastrophic disposal accidents by restricting disposal facility operations to the portion of the day when Pasquill stability categories E or F do not occur.

PAGE LEFT INTENTIONALLY BLANK

### 8.0 Risk Comparison

- a. Although the analysis performed in Section 7.0 indicated that it was possible to eliminate off post excursions resulting from internally initiated disposal facility Credible Catastrophic Accident scenarios by restricting operations to the portion of the day when Pasquill categories "E" and "F" do not exist, this approach does not address the more relevant concern of which operating scenario results in the lowest total risk to the public. This is because the analysis in Section 7.0 only examined the scenarios which were dependent on CSDP disposal facility operations and did not take into account the risks associated with the other activates associated with on-site disposal of the TEAD chemical stockpile.
- b. To determine which mode of CSDP disposal facility operations presents the lowest risk to the public three operating scenarios will be evaluated: restricted operations, unrestricted operations and partially restricted operations based on the results from Chapter 7. The total programmatic risk for each operating scenario will be determined based on the contributions from depot storage, handling and transportation, and disposal operations. Except for use in developing the partially restricted schedule, the results from Section Seven are not used in evaluating the total risk associated with the three operating scenarios. This is necessary to ensure the risks associated with disposal are treated on the same basis as the risks associated with storage and handling and transportation.

## 8.1 On-Site Disposal Alternative

- a. The onsite disposal alternative encompasses three activates, each with their own associated risks: Depot Storage (also referred to as continued storage); Intra-depot Handling and Transportation; and Disposal Operations.

  Up to this point, this study has only addressed the internally initiated or process dependent scenarios.
- (1) Depot Storage involves risks associated with storing and maintaining the chemical munitions in the existing facilities (igloos, warehouses and open storage in Area 10). The majority of the accident scenarios for depot storage are externally initiated by earthquakes, meteor strikes, plane crashes and other events which the storage personnel have little or no control over. Although the probability of these accidents is very small, the potential lethalities can be very large because of the quantity of chemical agent/munitions involved.
- (2) Handling and Transport involve all the activates associated with removing the munitions from their storage locations and placing them in the On-Site Container (ONC), ground convoy from the storage area (Area 10) to the disposal facility, and handling the munitions at the disposal facility prior to disposal. The majority of these accident scenarios are internally initiated involving vehicle accidents or dropped munitions.
- (3) **Disposal** includes all the operations and activates associated with disassembly, draining and incineration of the chemical agent and

munition. The accident scenarios are divided fairly evenly between internally initiated (process dependent) scenarios and externally initiated scenarios.

b. The two type of accident scenarios, externally and internally initiated, present different risks to the public. Internally initiated scenarios are based on the number of items/munitions and present a finite risk to the public, that is, the risk is not time dependent and remains fairly constant until the items are eliminated. Externally initiated events however, are primarily time dependent since they are initiated by events which the operating personnel have no control over. The public risk from externally initiated scenarios increases with time. The longer the items exist, the greater the risk to the public.

#### 8.2 <u>Disposal Schedule Options</u>

a. Figure 8-1 illustrates the three schedule options evaluated. Disposal operations begin 1 December 1992 and continue on a 5-day a week basis in accordance with the sequence shown in Table 8-1. The worksheet used to determine the total amount of time in hours to dispose of each munition is shown in Figure C-1. While it was attempted to adhere to the current scheduling philosophy/methodology, the schedules should be only viewed as representative of the duration of each option. For comparing the programmatic risks, the differences between the different option durations is more important than the actual duration of the options themselves.

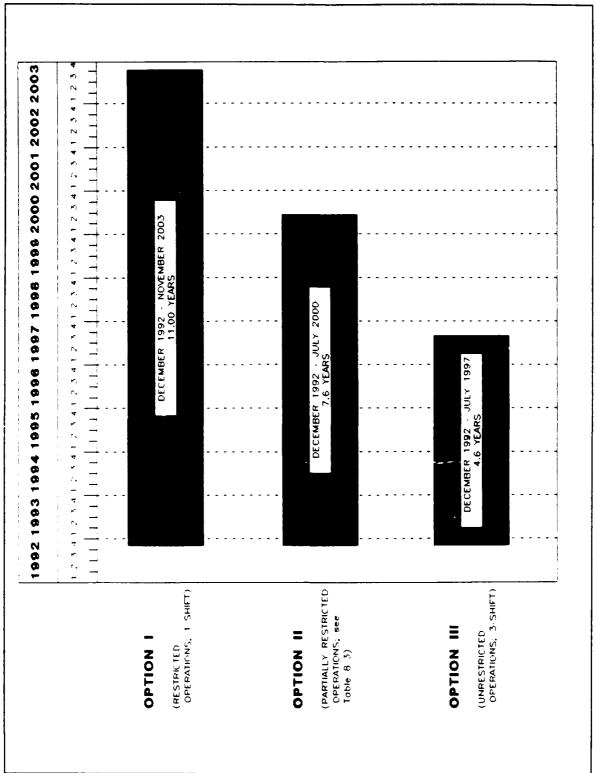

Figure 8-1: Meteorologically Restricted TEAD Stockpile Disposal Options

Table 8-1: TEAD Stockpile Disposal Sequence and Processing Rates

Munition Type		age ng Rates ons/hour)	Changeover Time
	Ramp	Disposal	(weeks)
M55 GB Rockets	N/A	32.00	3

M426 GB 8-in Projo	N/A	41.00	2
M360 GB 105mm Cart	93.00	186.00	2
M122 GB 155mm Projo	51.50	103.00	0
M121A1 GB 155mm Projo	N/A	103.00	4
M2A1 HT 4.2-in Mortar	87.50	175.00	2
M110 H 155mm Projo	69.50	139.00	0
M104 HD 155MM Projo	N/A	139.00	3
Ton Container - HD	0.60	1.20	6
M23 VX Land mines	29.50	59.00	6
TMU-28/B VX Spray Tank	0.39	0.77	2
Ton Container -VX	0.38	0.75	3
Ton Container - GB	N/A	1.00	2
Mkll6 "Weteye" GB Bombs	1.05	2.10	2
MC-1 GB Bomb	3.25	6.5	0

- (1) OPTION I is the restricted operating scenario and is synonymous with one-shift operations.
- (a) All disposal operations are performed during "Limited Daytime" which is the daylight hours when the atmospheric stability is neutral or lapse (Pasquill stability categories A-D). No operations would be performed when stable atmospheric conditions (Pasquill stability categories E and F) could exist. Based on the results from Section Six, only three

internally initiated disposal accidents could result in off-post excursions: PO-AGC-041, PO-KVC-042 and PO-SVC-042; however, as shown in Section Seven, the probability of an off-post excursion from these scenarios will be less than  $10^{-8}$  (0.00000001).

- (b) Because of the seasonal changes in sunrise and sunset, and consequently the changes in the occurrence of stable atmospheric conditions, the amount of hours available for disposal operations increases from a minimum of six hours in December to a maximum of 12 hours in June. Table 8-2 lists the operating periods for each month based on the Limited Daytime criteria. Note that the feasibility of operating a disposal facility on the schedule proposed in Table 8-2 is dubious at best, however, it represents the maximum time available for disposal operations while avoiding stable atmospheric conditions.
- (2) OPTION II is the partially restricted operating scenario and represents the operating scenario of interest to the Department of Health and Human Services and the state of Utah. In Option II, all disposal operations which could result in off post excursions from the TEAD internally initiated Credible Catastrophic Accidents (Table 7-3) are restricted to Limited Daytime, all other disposal operations are performed 24-hours per day. Table 8-3 summarizes the disposal strategy for this option, the scenario ID numbers are the scenarios which could result in off post excursions.
- (3) OPTION III is the unrestricted operating scenario and is synonymous with three shift disposal operations comparable to operating

Table 8-2: TEAD Restricted Operations Schedule ("Limited Daytime"; No Stable Meteorological Conditions)

MONTH	START OPERATION	STOP OPERATION	HOURS OF OPERATION

stockpile, Option II required 7.8 years and Option III only required 4.6 years.

### 8.3 Total Disposal Risk Determination.

a. To determine the total risk of each schedule option to the public, it is necessary to determine the associated risk contribution of each activity (depot storage, handling and transportation, and disposal). For the

comparison to be valid, the measure of risk for each activity must be based on a common database (population distribution, meteorological conditions, erc.). Since it was beyond the scope and charter of this study to evaluate the site specific meteorological and geographical impacts on the hazard distances associated with the storage, and handling and transportation Credible Catastrophic Accident scenarios, the FPEIS risk values (based on expected human fatalities) will be used to determine the risk contribution from each activity (storage, handling and transportation, and disposal). (NOTE: Expected Lethality is the product of the probability of the accident/event occurring multiplied by the potential average lethalities)

The manipulation of the FPEIS risk values is described below.

a. Depot Storage. The risks from depot storage occur in two phases. Before disposal operations begin, the annual risk from storage is assumed to be constant, however the storage risk during disposa! will decrease as the munition stockpile is destroyed. The actual rate of decrease is dependent on the agent and munition involved, however for use in this study, the storage risk during disposal is assumed to equal one-half the total storage risk for the same period of time. Equation three illustrates this relationship.

where: R<sub>annual</sub> - the total annual risk for a given munition. Table 8-4
lists the FPEIS storage scenarios which have expected

lethalities greater than zero. The composite risk for each munition/agent listed in Table 8-4 are shown in Table C-4 (Volume II) and were derived from the values listed in Table C-1 (Volume II).

T<sub>delay</sub> - the time delay in storage before the start of disposal operations. The values for T<sub>delay</sub> are listed in Tables C-8 through C-10 (Volume II).

T<sub>disposal</sub> - the time required to destroy the item stockpile. The
values for T<sub>disposal</sub> are listed in Tables C-8 through
C-10 (Volume II).

and R - the programmatic risk contribution for the specific munitions/agent.

### b. Handling and Transportation.

(1) At described in paragraph 8.1.a(2), three types of activities are included in "Handling and Transportation": handling at the disposal facility, depot handling away from the disposal facility and transportation from the storage area to the disposal facility. The FPEIS handling and transportation accident scenarios with expected lethalities greater than zero are listed in Table 8-5. The composite risks are contained in Table C-5 and were derived from the values listed in Table C-2 (Volume II). (NOTE: the handling accident scenarios associated with munition transfer from the Munition Holding Igloo (MHI) to the Multipurpose Demil Building (MDB) have been eliminated. This was performed to take credit for the improved safety

Table 8-4: FPEIS Continued (Depot) Storage and Handling Accident Scenarios (CS) With Expected Lethalities Greater Than Zero

Munition/ Agent	Scenario ID Number	Scenario Description
PG, QG, PV	HS-005	Drop of munition leads to detonation.
CG, PG, QG, PV	HS-007	Collision accident with prolonged fire.
PG, RG, MV, PV, RV	HS-011	Munition pallet dropped during pallet inspection; detonation occurs.
QG	SL-005	Large aircraft indirect crash onto storage area; fire not contained.
KG	SL-007	Severe earthquake breaches the munitions in storage igloos, no detonations.
KH, SV	SL-008	Meteorite strikes the storage area; fire occurs; munitions breached.
кн, sv	SL-015	Small aircraft direct crash onto open storage or warehouse, fire occurs, not contained in 30 minutes.
PG, QG, RG, MV, PV, QV, RV	SL-022	Severe earthquake leads to munition detonation.
PG, RG, MV, PV, RV	SL-025	Munition dropped during leaker isolation, munition detonates.
sv	SL-A27	Earthquake occurs, warehouse intact, munitions intact, fire occurs at one warehouse
sv	SL-B27	Earthquake occurs, warehouse intact, munitions intact, fire occurs at <u>two</u> warehouses.
sv	SL-C27	Earthquake occurs, one warehouse damaged, munitions intact, fire occurs at one
sv	SL-D27	warehouse. Earthquake occurs, one warehouse damaged, munitions intact, fire occurs at <u>two</u> warehouses.
sv	SL-E27	Earthquake occurs, two warehouses damaged, munitions intact, fire occurs at
sv	SL-F27	one warehouse. Earthquake occurs, two warehouses damaged, munitions intact, fire occurs at two warehouses.

Table 8-5: FPEIS Handling and Transportation Accident Scenarios (HT) With Expected Lethalities Greater Zero

Munition/ Agent	Scenario ID Number	Scenario Description
	HANDLING	AT THE DISPOSAL FACILITY
PG, QG, RG, MV, PV, QV, RV	HF-012	Drop of bare single munition inside the Munitions Demilitarization Building (MDB) leads to detonation.
ON-	SITE HANDLING	AWAY FROM THE DISPOSAL FACILITY
BG, KG	но-005	Drop of Onsite Container (ONC)
KG, SV	но-306	Forklift collision with short duration fire during handling of ONC.
BG, KG	но- 007	Forklift collision without fire during handling of ONC.
	ON-SI	TE TRANSPORTATION
KG	VO-001	A munition vehicle collision/overturn occurs and crush forces fail the agent containment.
KG	VO-003	A munition vehicle collision/overturn occurs and puncture forces fail the agent containment.
CG, PG, RG, MV, PV, RV	VO-004	A munition vehicle accident with fire occurs causing detonation of burstered munitions. Ignition of the propellant by a probe could also detonate the burster of a cartridge and the burster of a rocket could be detonated by impactinduced ignition of the rocket propellant.
RG	VO-012	A severe earthquake occurs causing a munitions vehicle accident and fire fails detonates burstered munitions.

associated with the Container Handling Building (CHB) which eliminates the need for the MHI.)

(2) Since depot handling and transportation will occur only during daylight hours regardless of the disposal facility operating schedule, the risks for these activities is assumed to occur equally for all schedule options. Disposal facility handling risks are treated in the same manner as internally initiated disposal risks described below.

### c. Disposal Operations.

- (1) Internally Initiated. The FPEIS internally initiated disposal accidents with expected lethalities greater than zero are listed in Table 8-7. Composite risks for each munition/agent listed in Table 8-6 are contained in Table C-6 and were derived from the values listed in Table C-2 (Volume II). Since accident scenarios PO-AGC-041, PO-KVC-042 or PO-SVC-042 are not listed in Table 8-6, the internally initiated disposal risks will be used only for those munitions processed on a unrestricted basis (24-hour/3-shift).
- (2) Externally Initiated. Like the risks associated with depot storage, risks created by externally initiated disposal accidents are time dependent. As long as the munitions are present in the disposal facility, the risks are present. The accident scenarios with expected lethalities greater than zero are listed in Table 8-7. The annual composite risks for each agent munition listed in Table C-7 are not classified but are contained in

Table 8-6: FPEIS Internally Initiated Disposal Accident Scenarios (DI)
With Expected Lethalities Greater Than Zero

Munition/ Agent	Scenario ID Number	Scenario Description
KG	PO-042	Metal Parts Furnace (MPF) explosion due to failure to stop fuel flow after a shutdown.
PG, RG, PV	PO-049	Munition detonation in Explosion Containment Room (ECR) causes structural and ventilation system failure.
RG	PO-050	Munition detonation in ECR causes structural failure, a fire and ventilation failure.
RG, MV, RV	PO-052	A burstered munition is fed to the Dunnage Incinerator (DUN)

Appendix C for completeness. The individual annual risks were calculated by multiplying the accident probabilities from Appendix I.1.4 of the GA Technologies risk study<sup>2</sup> by the average lethalities listed in "Consequence Estimates; Potential Fatality Estimates; Average Population Density" File CNSPO contained Volume Two of the MITRE Corporation risk analysis<sup>3</sup>. The sum of the individual annual risks for a specific munition/agent is the composite risk.

Table 8-7: FPEIS Externally Initiated Disposal Accident Scenarios (DE)
With Expected Lethalities Greater Than Zero

Munition/ Agent	Scenario ID Number	Scenario Description
KG, KV, SV	PO-025	Earthquake damages the Munitions Demilitarization Building (MDB) structure, munitions fall and are punctured, fire suppressed.
BG, SV	PO-026	Earthquake damages the MDB structure; munitions fall and are punctured; earthquake also initiates fire; fire suppression system fails.
BG, CC, KG, PG, QG, RG, DH, KH, PH, MV, KV, PV, RV, SV	PO-029	Earthquake damages the MDB; munitions are intact; fire occurs; fire suppr. sion system fails.
CG, PG, QG, RG, DH, PH, MV, PV, RV	PO-033	Earthquake causes munitions to fall but no detonation occurs; the MDB is intact; the Toxic Cubicle (TOX) is intact; earthquake also initiates fire; fire suppression fails.

### 8.4 <u>Total Disposal Risk Comparison</u>.

a. Table 8-8 summarizes how the risks associated with depot storage, handling and transportation, and disposal were used to determine the total risk for each schedule option. The risks associated with depot storage and externally initiated disposal accidents are applied equally to all three scenarios. The risks associated with handling and transportation and disposal are dependent on whether the munitions are processed at the disposal facility

Table 8-8: Applicability of Individual Activity Risks to the Total Disposal Risk

	Schedule Option		
Source of Risk	Option I (Restricted)	Option II (Partially Restricted)	Option III (Unrestricted)
CS	х	х	х
DI		(1)	X
DE	x	X	X
нт	(2)	(3)	X

Notes:

- (1) Only for those munitions processed on a unrestricted basis.
- (2) Depot handling and transportation only.
- (3) Depot handling and transportation plus disposal facility handling for munitions processed on a unrestricted basis.
- CS Depot/Continued Storage Accidents
- HT Handling and Transportation Accidents
- DI Internally Initiated Disposal Accidents
- DE Externally Initiated Disposal Accidents

on a restricted or unrestricted basis.

b. The programmatic risks for each schedule option are summarized in Table 8-9 with the detailed calculations shown in Figures C-2 through C-4. Figure 8-2 illustrates the relationship of the programmatic risks for each schedule option. Four things stand out clearly:

Table 8-9: Total and Major Activity Risks for TEAD CSDP Disposal Facility Operating Schedule Options

	Se	chedule Options	
Risk	Option I	Option II	Option III
Total	3.77 x 10 <sup>-4</sup>	2.53 x 10 <sup>-4</sup>	1.87 x 10 <sup>-4</sup>
cs	2.85 x 10 <sup>-4</sup>	$1.68 \times 10^{-4}$	$1.22 \times 10^{-4}$
DI	υ	0	$2.14 \times 10^{-6}$
DE	5.70 x 10 <sup>-5</sup>	$4.39 \times 10^{-5}$	$2.05 \times 10^{-5}$
нт	3.51 x 10 <sup>-5</sup>	4.06 x 10 <sup>-5</sup>	$4.25 \times 10^{-5}$

Notes: CS - Depot/Continued Storage Accidents

HT - Handling and Transportation Accidents
DI - Internally Initiated Disposal Accidents
DE - Externally Initiated Disposal Accidents

Option I - Restricted Disposal Operations

(1-Shift Operations)

Option II - Partially Restricted Disposal Operations

Option III - Unrestricted Disposal Operations (3-Shift Disposal Operations)

- (1) The total risk to the public, reardless of which schedule option is selected, is <u>very small</u>.
- (2) The total risks for the schedule options are essentially equal, having the same order of magnitude  $(10^{-4})$ . Although the total risk for Option III is only 49% of the total risk for Option I and 74% of the total

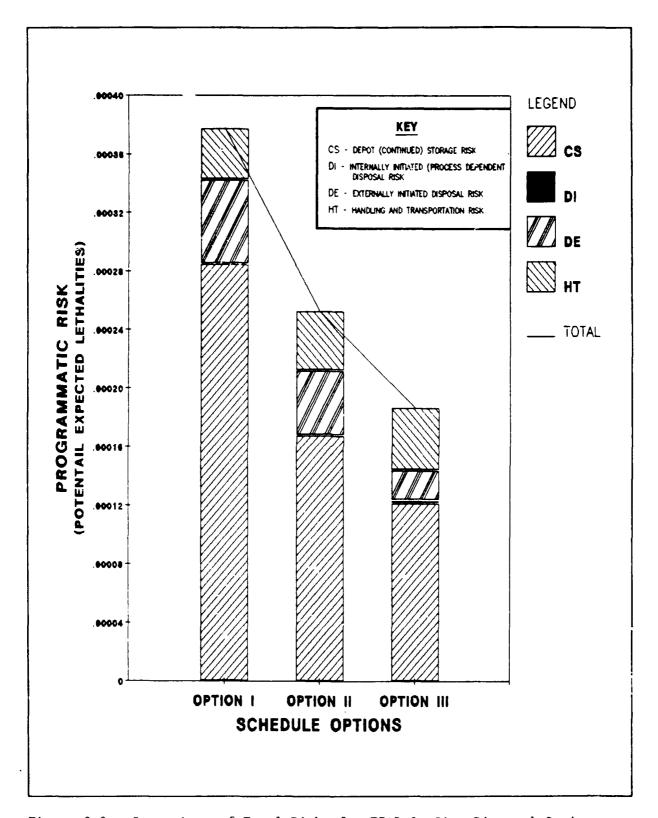

Figure 8-2: Comparison of Total Risks for TFAD On-Site Disposal Options

risk for Option II, the differences are within the accuracy of the calculations.

- (3) The risks associated with depot storage represent the predominate risk for each schedule option, with risks one to two orders of magnitude greater than the risks associated with the other activities. This is especially true for Option I where the depot storage risk alone is greater than the total risks for either Option II or Option III.
- (4) The risks associated with internally initiated disposal operations represent the least risk to the public.
- c. Although restricted disposal operations eliminates the risks associated with the internally initiated disposal accident scenarios, this reduction is very small compared to the risks associated with the other activities associated with on-site disposal. The relationship of the major activity risks to the programmatic risks is illustrated in Figure 8-3, where even in Option III, the internally initiated disposal risks only represent 1% of the total programmatic risks as compared to 65% for depot storage, 23% for handling and transport and 11% for the externally initiated disposal risks.

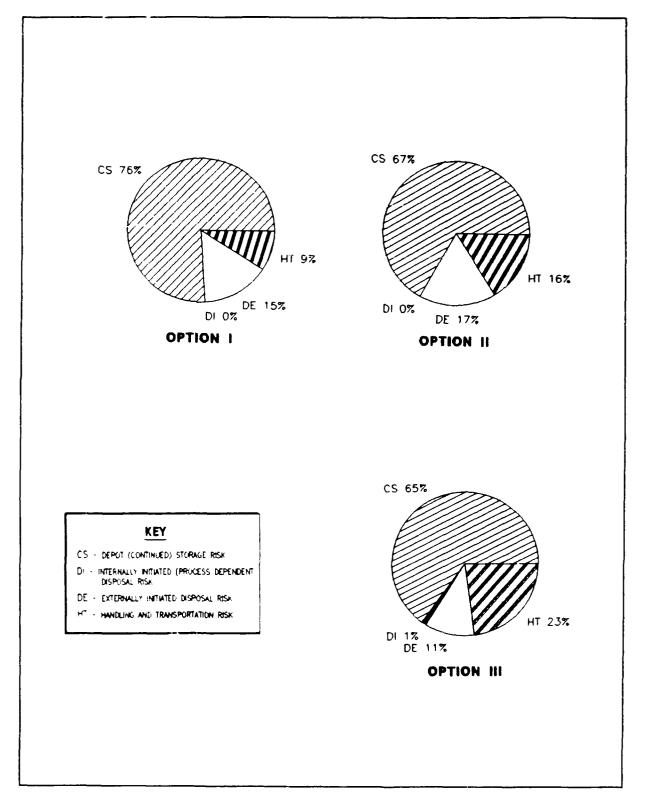

Figure 8-3: Relative Contributions to Total TEAD On-site Disposal Risk

### 9.0 Conclusions and Recommendations.

The purpose of this study was to examine the TEAD site specific meteorological, chronological and geographical effects on the hazard distances associated with the internally initiated (process dependent) disposal process Credible Catastrophic Accidents used in the CSDP Final Programmatic Environmental Impact Statement (FPEIS) and to determine which operating scenario represented the lowest total risk to the public.

### 9.1 Meteorological Effect on Accident Scenarios.

Of the 26 FPEIS internally initiated disposal Credible Catastrophic Accident scenarios, only 11 continue meet the definition of a Credible Catastrophic Accident (CCA) after TEAD site specific geographical and meteorological conditions are taken into account (i.e.  $10^{-8}$  probability or greater of creating a downwind hazard distance which exceeded the installation boundary).

- a. Five of the 15 non-CCA scenarios involve GB filled cartridges and Mustard filled ton containers which result in hazard distances less than the distance to the TEAD South Area installation boundary. The remaining ten non-CCA scenarios have off-post excursion probabilities of less than  $10^{-8}$ .
- b. The 11 CCA scenarios only exist under stable atmospheric conditions (Pasquill stability categories E and F), therefore it is possible to eliminate the CCA scenarios by restricting disposal facility operations to the portions

of the day when these conditions do not exist (i.e. from two hours after sunrise to one hours before sunset). It should be noted however, that <u>simply restricting disposal facility operations to non-stable meteorological conditions will not prevent off-post excursions</u> because three accident scenarios (PO-AGC-041, PO-KVC-042 AND PO-SVC-042) create off-post excursions during neutral atmospheric conditions (Pasquill stability category D) which can occur 24-hours per day, and it is these three scenarios which create the largest hazard distances under <u>any</u> atmospheric conditions. To ensure these scenarios do not create off-post hazards, operations would have to be further limited to when the wind was equal to or greater than 3.1 knots (1.6 meters per second) or to when the net radiation index is equal to or greater than 2. The later condition occurs when the solar altitude is at least 15° and the cloud cover is less than or equal to 50%.

c. Although the impact can not be evaluated quantitatively, restricting disposal operations to less than 24-hours per day will have an adverse impact on the probability of an agent release. It is widely recognized that the safest portion of an automated process is when the equipment is operating automatically and operator involvement is minimized. This is true not only for nuclear power plants and commercial petro-chemical facilities but for chemical munition disposal facilities as well. By starting and stopping the disposal process each day, the potential of an agent release might be increased by a factor of five as compared to starting and stopping the process once a week as currently proposed.

### 9.2 Impact on Total Risk.

Although the risk to the public from internally initiated CCA scenarios can be mitigated by restricting disposal operations, the true measure of public safety is the total risk which the operation presents to the public.

The total risk associated with on-site disposal is dependent on the risks from depot storage, munition handling and transportation, as well as disposal operations.

- a. The total risk to the public from the disposal of the TEAD chemical stockpile is very small, with expected lethalities on the order of 10-4 (0.0001). Stated another way, one fatality can be expected every 10,000 times the TEAD stockpile is destroyed. Although the total risk from unrestricted operations was only 49% and 74% of the total risks for restricted and partially restricted operations respectively, the differences are within the accuracy of the calculations. The predominate risk for all three operating scenarios is the risk associated with depot storage which ranges from 65 to 76 percent of the total risk associated with disposal of the TEAD chemical stockpile.
- b. Regardless of which operating scenario is considered, restricted, unrestricted or partially restricted, the internally initiated disposal accidents only represent a maximum of one-percent of the total risk.

  Therefore, focusing on mitigating internally initiated disposal accidents will produce the smallest decrease in the total risk to the public and depending on

the methods used (i.e. restricting operations) could actually increase the risk to the public.

c. Although the effects of shift work on the performance of the operators can not be quantified, a penalty factor of twice the risk is commonly assessed to multi-shift operations. Even if this penalty is assessed to the risks associated with internally initiated disposal accidents, the results of the study are unaffected.

### 9.3 Recommendations.

- a. TEAD CSDP disposal facility operations should not be restricted on the basis of stable meteorological conditions. Not only would the duration of the disposal program be extended by 3.2 to 6.4 years, but there is no reduction in the total risk to the public by restricting or partially restricting disposal operations.
- b. Evaluate optimizing the disposal schedule to accelerate the disposal of the munitions which present the greatest storage risk. The risks associated with chemical munition storage are significantly greater than the risks associated with any other disposal activity. Since the accidents associated with storage are predominately externally initiated, the sooner the munitions are destroyed, the smaller the risk to the public. Table 9-1 lists the munitions in descending order of storage risk.

Table 9-1: Munition Ranking in Terms of Storage Risk (Descending Risk)

Munition/Container	Agent Fill
Spray Tank	vx
155mm Projectile	GB
155mm Projectile	vx
105mm Cartridge	GB
Ton Container	GB
115mm Rocket	GB
115mm Rocket	vx
Land Mine	vx
Ton Container	HD
8-in Projectile	GB
8-in Projectile	vx

c. Evaluate limiting handling away from the disposal facility and/or transportation from the storage area to the disposal facility to the portion of the day when stable meteorological conditions do not exist. However, this restriction should only be implemented if the additional loss of two to three hours per day does not impede disposal operations (i.e. extend the duration of the disposal program), otherwise any reduction realized by restricting handling and transportation activities could be offset by increases in the depot storage risk. In any event, unless significant reductions in the risk

associated with depot storage are realized, the resulting 23% reduction in the total risk created by restricting handling and transportation activities will be insufficient to affect the magnitude (i.e.  $10^{-4}$ ) of the total risk.

### TABLE B-3. CHEMICAL AGENT TABUN (GA) CHARACTERISTICS

### **GENERAL:**

GA is an anticholinesterase agent similar in action to GB (q.v.). Although only about half as toxic as GB by inhalation, GA in low concentrations is more harassing to the eyes than GB. Individuals poisoned by GA display approximately the same sequence or symptoms regardless of the route by which the poison enters the body (whether by inhalation, adsorption, or ingestion). These symptoms, in normal order of appearance, are: runny nose; tightness of chest; dimness of vision and pinpointing of the eye pupils; difficulty in breathing; drooling and excessive sweating; nausea; vomiting; cramps; and involuntary defectation and urination; twitching; jerking; and staggering; and headache; confusion; drowsiness; coma; and convulsion. These symptoms are followed by cessation of breathing and death.

### PHYSICAL PROPERTIES:

- a. Chemical Name: Ethyl N, N-dimethylphosphoramido-cyanidate
- b. Chemical Formula: Empirical. C<sub>5</sub>H<sub>11</sub>N<sub>2</sub>O<sub>2</sub>P
- c. Molecular Weight: 162.1
- d. Vapor Density, Relative to Air: 5.6
- e. Liquid Density: 1.08 g/ml @ 25°C
- f. Normal Freezing Point or Melting Point: -50°C
- g. Boiling Point: 245°C
- h. Vapor Pressure: 0.07 mm Hg @ 25°C
- i. Flash Point: 78°C
- j. Viscosity (centistokes @ 25°C): 2.18
- k. Color: Colorless to brown
- 1. Odor: Faintly fruity; none when pure
- m. Special Properties: None
- n. Solubility Properties: Readily soluble in most organic solvents
- o. H Combustion: 9,751 BTU/1b
- p. Physical State: Viscous Liquid

### TABLE B-4. CHEMICAL AGENT SARIN (GB) CHARACTERISTICS

### **GENERAL:**

GB is a rapid-acting lethal nerve agent. The action within the body is the inactivation of cholinesterase. The hazard from GB is that of vapor adsorption through the respiratory tract, although it can be absorbed through any part of the skin, through the eyes, and through the gastrointestinal tract by ingestion. The agent absorption rate is accelerated through cuts and abrasions in the skin. When dispersed as large droplets, GB is moderately persistent; it is nonpersistent when disseminated as a cloud of very fine particles.

### PHYSICAL PROPERTIES:

- a. Chemical Name: Isopropylmethylphosphonofluoridate. Sarin.
- b. Chemical Formula: C4H10FO2P
- c. Molecular Weight: 140.10
- d. Vapor Density (Air = 1.00): 4.36
- e. Liquid Dersity at 25°C: 1.0887 gm/cc
- f. Freezing Point: -56°C
- g. Boiling Point: 158°C
- h. Vapor Pressure: 2.9 mm Hg @ 25°C
- i. Flash Point: Does not flash
- j. Viscosity (centistokes @ 25°C): 1.28
- k. Color: Clear to straw to amber
- 1. Odor: None
- m. Special Properties: None
- n. Solubility Properties: Miscible with water and readily soluble in all organic solvents
- o. H Combustion: 10,000 Btu/1b
- p. Physical State: Viscous Liquid

DICIDI and TBA are not both in all GB.

### TABLE B-5. CHEMICAL AGENT VX CHARACTERISTICS

### **GENERAL:**

VX is a rapid-acting lethal nerve agent. The action within the body is the inactivation of cholinesterase. The hazard from VX is primarily that of liquid absorption through the skin, although it can be adsorbed through the respiratory tract as a vapor or aerosol, and through the gastrointestinal tract by ingestion. VX is slow to evaporate and may persist as a liquid for several days.

### PHYSICAL PROPERTIES:

- a. Chemical Name: 0-ethyl S-(2-diisopropylaminoethyl)
  Methylphosphonothiolate
- b. Chemical Formula: C<sub>11</sub>H<sub>26</sub>NO<sub>2</sub>PS
- c. Molecular Weight: 267.37
- d. Vapor Density (Air = 1.0): 9.2
- e. Liquid Density at 25°C: 1.008 gm/cc
- f. Freezing Point: Below -39°C
- g. Boiling Point: 300°C
- h. Vapor Pressure @ 20°C: 0.0006 mm Hg
- i. Flash Point: 159°C
- j. Viscosity (centistokes @ 25°C): 9.96
- k. Color: Clear to straw
- 1. Odor: None
- m. Special Properties: None
- n. Solubility Properties: Best solvents are dilute mineral acids
- o. H Combustion: 15,000 Btu/1b
- p. Physical State: Viscous Liquid

These numbers are given as a guide only and do not represent product specifications or the exact constituency of the agent.

Dicyclohexylcarbodiamide is an alternate stabilizer.

### TABLE B-6. CHEMICAL AGENT MUSTARD (H/HD/HT) CHARACTERISTICS

### **GENERAL:**

Mustard is a persitent and powerful blistering agent. It acts principally by poisoning the cells in the surfaces contacted. Both liquid and vapor cause intense inflammation and may cause severe blistering of both the skin and mucous membranes. Mustard is only moderately volatile.

Mustard is designated H, HD, and HT. H is mustard made by the Levinstein process. It contains up to 25 percent by weight of impurities, chiefly sulfur, organosulfur chlorides and polysulfides. HD (distilled mustard) is mustard purified by washing and vacuum distillation, which reduces impurities to about 5 percent. HT is a 60:40 mixture by weight of HD and T. T is an abbreviation for  $\frac{1}{2}(2-\text{chloroethylthio})\text{ethyl}\frac{1}{2}$  ether.

### PHYSICAL PROPERTIES:

a. Chemical Name: Bis (2-chloroethyl) sulfide

2,2'- dichlorodiethyl sulfide- sulfur mustard

#### TABLE B-7. CHEMICAL AGENT LEWISITE (L) CHARACTERISTICS

#### **GENERAL:**

L is a vesicant. It produces effects similar to HD but, in addition, acts as a systemic poison, causing pulmonary edema, diarrhea, restlessness, weakness, subnormal temperature, and low blood pressure. In order of severity and appearance of symptoms, it is: a blister agent, a toxic lung irritant, and when absorbed in the tissues, a systemic poison. Liquid L causes an immediate searing sensation in the eye and permanent loss of sight if not decontaminated within 1 minute. L produces an immediate and strong stinging sensation to the skin; reddening of the skin starts within 30 minutes. Blistering does not appear until after about 13 hours. Like HD, it is a cell poison. Skin burns are much deeper than with HD. When inhaled in high concentrations it may be fatal in as short a time as 10 minutes. The body does not detoxify L.

### PHYSICAL PROPERTIES:

- a. Chemical Name: Dichloro-2-chlorovinylarsine, lewisite
- b. Chemical Formula: C2H2AsCl3
- c. Molecular Weight: 207.32
- d. Vapor Density: 1.88 g/ml @ 25°C
- e. Solid Density:
  - 1) Bulk Density: Not applicable
  - 2) Crystal Density: Not applicable
- f. Normal Freezing Point or Melting Point:  $-18^{\circ}\text{C}$  +/-  $0.1^{\circ}\text{C}$ , depending on (purity and isomers present)
- g. Boiling Point: 190°C
- h. Vapor Pressure: 0.58 mm Hg @ 25°C
- i. Flash Point: Does not flash
- j. Viscosity: 1.09 centistokes @ 25°C
- k. Color: Amber to dark brown
- 1. Odor: Usually geranium like, very little odor when pure
- m. Special Properties: None

# TABLE B-7. CHEMICAL AGENT LEWISITE (L) CHARACTERISTICS (Con't)
